

Eribé Knitwear

BlueCherry ERP Data Migration

Intake Workbook

User Guide — Step-by-Step Instructions

What is this guide for?

This guide walks you through completing the **Eribé migration intake workbook** — an Excel spreadsheet that captures all the information needed to migrate Eribé Knitwear's data into BlueCherry ERP.

You do **not** need any technical knowledge to complete this. Your job is to gather the right information from the people who know the data — this guide tells you exactly what to ask and where to write it.

For:	Andrew Scott & Carolyn Scott
Prepared by:	Caracal Lynx Limited
Project:	Eribé Knitwear → BlueCherry ERP Migration
Questions?	Contact Michael Scott

This document is confidential and prepared solely for use by Caracal Lynx Limited and its authorised representatives.

Overview

The intake workbook is an Excel file with **five data-entry tabs** and a reference tab. You work through them **left to right**, completing each one before moving to the next. The information you collect will be used to automatically generate the technical configuration files needed to run the migration — you don't need to understand those files at all.

The Five Tabs at a Glance

Tab Name What you'll fill in Time			
1	Entity & Source	Which type of data this is (e.g. Styles), where it comes from	5–10 min
2	Source Columns	A list of every column in the source data with example values	10–20 min
3	Field Mappings	How each source column maps to a BlueCherry column	20–40 min
4	DQ Rules	Rules for what counts as valid data (e.g. price must be > 0)	10–20 min
5	Lookups	Translation tables (e.g. old division code W = WOMENS in BlueCherry)	5–15 min

Colour Key — What the Cell Colours Mean

The workbook uses three cell colours to tell you what to do with each cell:

Colour	Meaning	What to do
★ Yellow	Free text entry	Click the cell and type your answer directly
◆ Blue	Dropdown selection	Click the cell and choose from the dropdown list that appears
Grey	Pre-filled / read only	These cells are filled in for you — do not change them

The ★ Symbol — Required Fields

Column headers marked with a ★ (**star**) are required — you must fill them in. The migration cannot proceed if required fields are left blank. If you genuinely don't know the answer, write ? in the cell and add a note — Michael will follow up.

✓ TIP

It is always better to write '?' than to guess. A wrong answer causes problems later; a question mark gets resolved quickly.

One Workbook Per Entity

Each workbook covers **one type of data** — for example, all of Eribé's style records, or all of their vendor records. If you are migrating both Styles and Vendors, you will need two separate copies of the workbook, each renamed to match the entity:

→ EXAMPLE

eribe-style-intake.xlsx — for the Style entity
eribe-vendor-intake.xlsx — for the Vendor entity

The six entity types available in BlueCherry are: **Style, Vendor, PurchaseOrder, PODetail, Season, ColourSize**. You will select the correct one on Tab 1.

Before You Start

What You Will Need

- A copy of the intake workbook file (eribe-migration-intake.xlsx)
- Access to the Eribé data — ideally a sample export or report
- A meeting (or session) with the person at Eribé who knows this data best
- About 1–2 hours per entity type

Preparing for the Data Owner Meeting

The **data owner** is the person at Eribé who works with this data day-to-day — for example, the person who manages styles or raises purchase orders. You do not need them to understand BlueCherry or the technical side; you just need them to explain what their current data looks like.

Useful questions to ask them:

“Can you show me an export or report of this data?”	Even a screenshot is helpful. Real data is far better than descriptions.
“What does each column mean?”	Ask them to walk through the columns one by one — fill in Tab 2 as they explain.
“Are there any columns that are sometimes blank?”	This affects the data quality rules you set in Tab 4.
“For code fields, what are all the possible values?”	E.g. for Division: is it always W, M, or A? Could it be anything else?
“Is there anything messy or inconsistent in this data?”	Old systems often have gaps, typos, legacy codes — better to know upfront.

! IMPORTANT You don't need to complete the workbook in one session

It is fine to fill in what you can, flag uncertain answers with '?', and come back to it. Michael will review before running anything.

Saving Your Copy

Before you start filling in the workbook, **save a new copy** with a name that identifies the entity you are working on:

→ EXAMPLE

Original file: eribe-migration-intake.xlsx

Your copy: eribe-style-intake.xlsx (or eribe-vendor-intake.xlsx, etc.)

i NOTE

Keep the original file untouched so you can make further copies for other entities.

TAB

1

Entity & Source

Tell us what data you are migrating and where it lives

This tab sets up the basics: which BlueCherry entity you are migrating, where the source data comes from, and where the output file should go. Most fields here have dropdowns — just click and select.

Step-by-Step

1

Select the BlueCherry Entity Type

Click the blue dropdown cell next to 'BlueCherry Entity Type'.

Choose the entity that matches the data you are migrating:

Style / Vendor / PurchaseOrder / PODetail / Season / ColourSize

If you are not sure which one, ask Michael before continuing.

2

Enter the Pipeline Name

Type a short name for this migration job.

Rules: lowercase letters and hyphens only. No spaces, no capitals.

Good examples: eribe-styles eribe-vendors eribe-purchase-orders

Bad examples: Eribe Styles ERIBE_STYLES eribe styles

3

Set the Version

Type: 1.0

Leave the quotes off — just type 1.0 in the cell.

4

Write a Description

One or two plain-English sentences describing what this migration does.

Example: Style master data migration from legacy CSV exports to BlueCherry ERP

This appears in reports and log files — it helps Michael and future users understand what the pipeline does at a glance.

5

Fill in your name and today's date

These fields are optional but help us track who completed which section and when.

6

Select the Source Adapter

This tells the system how to read the source data. Click the blue dropdown and choose:

mssql — the data is in a SQL Server database

csv — the data is in a CSV file (comma-separated text)

xlsx — the data is in an Excel spreadsheet

pg — the data is in a PostgreSQL database

If you are not sure, ask the Eribe IT contact.

7

Enter the Connection or File Path

For a CSV or Excel file: type the filename or path to the file.

Example: `./data/styles-export.csv`

For a database: leave this as `${ERIBE_MSSQL}` — Michael will configure the connection separately.

8

Enter the SQL Query (database sources only)

If the source is a SQL Server or PostgreSQL database, paste the SQL SELECT query here.

This is the query that pulls the records from the source database.

If the source is a CSV or Excel file, leave this blank.

9

Set the Output File Path

This is where the BlueCherry import file will be written.

Example: `./output/eribe-styles-bc.csv`

Keep the same naming pattern — replace 'styles' with the entity name.

10

Note any open questions

Use the last field on this tab to note anything you are unsure about.

Write a ? before each question so Michael can spot them easily.

✓ TIP Common source adapters for Eribé

Most Eribé data will be `csv` (exported from their legacy system) or `mssql` (read directly from their SQL Server database). Check with the data owner.

TAB

2

Source Columns

List every column in the source data with example values

This tab builds a profile of the source data. You will list every column that exists in the source (the database table or CSV file), along with example values and notes. This helps Michael understand the shape of the data before building the mappings.

i NOTE

The best way to complete this tab is to ask the data owner to share a sample export — even 5-10 rows is enough. You can then copy the column names directly from the file.

Step-by-Step

1

Get a sample of the data

Ask the data owner: 'Can you export 10-20 rows of this data for me?'
A CSV export or Excel file is ideal. Even a screenshot of a report will do.
Open the sample alongside the workbook so you can copy column names easily.

2

Enter each Source Column Name

In the yellow 'Source Column Name' column, type the exact name of each column as it appears in the source data — including capitalisation.
Examples: STYLE_NO StyleDesc cost_price Active
Do not change the spelling — exact names are required for the system to find them.

3

Select the Data Type

Click the blue dropdown and pick the closest match:

- Text — words, names, codes, descriptions, postcodes
- Integer — whole numbers (e.g. quantity: 5, 10, 100)
- Decimal — numbers with decimal places (e.g. price: 12.50)
- Date — dates (e.g. 01/06/2024)
- Boolean — yes/no or true/false values
- Unknown — not sure — that's fine, note it in the Notes column

4

Add 2-3 Example Values

Copy real values from your sample data into the three example columns.
These help Michael check his understanding and spot potential issues.
For a Style Number column, examples might be: SS24-001 AW23-142 SS24-099

5

Note whether the column can be blank

Click the dropdown and select Yes (sometimes blank) or No (always has a value).
If you are not sure, select Yes — it is safer to assume blanks are possible.

6

Note whether values are always unique

Select Yes if every row has a different value (like an ID or code).

Select No if the same value can appear in multiple rows (like a Division code).

7

Add any notes or issues

Use the Notes column to flag anything unusual:

'? Sometimes has leading spaces'

'Values used to be uppercase, now mixed case'

'Some rows have NULL here for older records'

'Not sure what this column is for'

8

Repeat for every column — including ones you won't migrate

List ALL columns, even if you don't think they need to be migrated.

In the Notes column, write 'Not migrating' for columns to skip.

It is much easier for Michael to exclude a column than to add one he didn't know about.

✓ TIP Ask for a data dictionary

Some systems have a 'data dictionary' or 'field list' document that describes every column. If Eribé has one, it can save a lot of time on this tab.

TAB
3

Field Mappings

Connect each source column to its BlueCherry equivalent

This is the most important tab. For each piece of data that needs to appear in BlueCherry, you specify which source column it comes from and how it should be handled. Check the **REF tab** in the workbook for the required BlueCherry columns for your entity.

! IMPORTANT

Every required BlueCherry column for your entity **MUST** have a mapping.
Required columns are listed in the REF tab of the workbook.

Understanding the Columns

Column What to enter	
Source Field(s) ★	The column name(s) from your source data (from Tab 2)
Target Field ★	The BlueCherry column name this maps to (from the REF tab)
Mapping Type ★	How to handle the value — select from dropdown (see table below)
Max Length	Maximum characters allowed — only needed for Text fields
Decimal Precision	Decimal places — only needed for Decimal fields (e.g. 2 for prices)
Date Format	Source date format if not standard — e.g. DD/MM/YYYY
Default Value	Value to use when source is blank or null
Optional?	No = required (error if blank); Yes = OK to be blank
Cleanse Operations	Automatic fixes to apply — e.g. trim (remove spaces) or uppercase
Lookup Name	If type is 'lookup', which lookup table to use (from Tab 5)

Mapping Types — Which One to Choose?

Type Use when Example		
string	Mapping a text or code value directly	STYLE_NO → StyleNo
number	Mapping a whole number (integer)	QTY → Quantity
decimal	Mapping a price or other decimal value	COST_PRICE → CostPrice (precision 2)
boolean	Mapping a yes/no or active/inactive flag	IS_ACTIVE → Active

date	Mapping a date field	ORDER_DATE → OrderDate (format DD/MM/YYYY)
lookup	The source value needs translating to a BlueCherry code	DIVISION → Division (via divisionMap)
concat	Combining two or more source columns into one	ADDR1 + ADDR2 → Address
constant	Every row should get the same fixed value	ActiveFlag = Y (always)
expression	Complex calculation — ask Michael	Computed field — note requirement in the Notes column

Step-by-Step

1

Check the required columns for your entity

Open the REF tab and find your entity type in the 'Required BlueCherry Columns' table. These columns **MUST** be mapped — make a note of them before you start.

2

For each required BlueCherry column, find the matching source column

Work down the list of required columns. For each one, ask:
'Which column in the source data contains this information?'
Write the source column name in the 'Source Field(s)' column (★ yellow cell).

3

Enter the Target Field name

Type the BlueCherry column name in the 'Target Field' column.
Use the exact name from the REF tab — capitalisation matters.
Example: StyleNo (not style_no or STYLENO)

4

Select the Mapping Type

Click the blue dropdown and choose the appropriate type (see table above).
For most text and code fields: string
For prices: decimal For quantities: number For dates: date
For translated codes (e.g. division): lookup

5

Fill in any type-specific fields

Decimal fields: enter the decimal precision (e.g. 2 for prices)
Date fields: enter the source date format (e.g. DD/MM/YYYY)
Lookup fields: enter the lookup name from Tab 5

6

Set a Default Value if needed

If the source value can sometimes be blank, what should BlueCherry receive instead?
Example: if Country is blank, default to GB
Leave empty if there is no sensible default.

7

Set Optional to Yes or No

No = this field must have a value — rows without it will be rejected

Yes = it is OK for this field to be blank in some rows

8

Add any Cleanse Operations

Cleanse operations automatically fix common data issues. The most useful ones are:

trim — removes extra spaces at start and end (use on almost everything)

uppercase — converts to UPPERCASE

titleCase — converts to Title Case (good for names)

normaliseUnicode — converts accented characters (e.g. e-acute → e)

Separate multiple operations with a pipe: trim|uppercase

See the REF tab or Tab 3's quick reference for the full list.

9

Add extra mappings for any additional columns

After the required columns, add rows for any other source columns that should appear in BlueCherry — even if they are optional.

Leave rows blank for source columns that should NOT be migrated.

✓ TIP When in doubt, map it

If you are not sure whether a source column should be migrated, add a row for it anyway and note your uncertainty. It is easier to remove a mapping than to add one later.

TAB
4

DQ Rules

Define what 'good' data looks like — bad rows are flagged before reaching BlueCherry

DQ stands for **Data Quality**. This tab lets you define rules that check the source data before it is migrated. Rows that fail a *critical* rule are rejected and not migrated. Rows that fail a *warning* rule are flagged in a report but still migrated.

Severity What happens Use for		
CRITICAL	Row is rejected — not migrated to BlueCherry	Fields that must have a value; codes that must be valid
WARNING	Row is flagged in the DQ report but still migrated	Data quality issues that don't block migration
INFO	Noted in summary report only	Informational counts — no action needed

Rule Types

Rule Type What it checks Rule Value needed?		
notNull	Value must not be blank or empty	No
unique	Value must not repeat — each row must be different	No
maxLength	Value must not be longer than N characters	Yes — enter N e.g. 20
min	Number must be at least N	Yes — enter N e.g. 0
max	Number must be no more than N	Yes — enter N e.g. 9999.99
allowedValues	Value must be one of a specific list	Yes — comma-separated list e.g. WOMENS,MENS,ACCESSORIES
pattern	Value must match a format (e.g. style code format)	Yes — ask Michael to write the pattern for you
email	Value must be a valid email address	No
ukPostcode	Value must be a valid UK postcode	No

Step-by-Step

1

Look at the example rules in green

The workbook has pre-filled example rules for the Style entity in green. Read through them to understand the pattern — each row is one rule for one field. When you add your own rules, work in the rows below the green section.

2

Identify which fields need rules

Start with the most important fields — the ones used as identifiers or keys. Every field that is marked as required in Tab 3 should have at least a `notNull` rule. Fields that should be unique (like a style code) should also have a `unique` rule.

3

Enter the Source Field Name

Type the column name from the source data — exactly as it appears in Tab 2. This must match exactly (capitalisation included).

4

Select the Rule Type

Click the blue dropdown and select the rule type from the list. For most required fields, start with `notNull` and add others as needed.

5

Enter the Rule Value (if required)

Some rules need a value:

`maxLength` — type the maximum number of characters (e.g. 20)

`min/max` — type the minimum or maximum number (e.g. 0 or 9999.99)

`allowedValues` — type all allowed values separated by commas (e.g. WOMENS,MENS,ACCESSORIES)

`pattern` — leave blank and note what format is needed; Michael will write the regex

6

Select the Severity

Click the blue dropdown:

`CRITICAL` — for rules where a failure means the row cannot be migrated

`WARNING` — for rules where a failure is worth noting but migration can continue

When in doubt, use `WARNING` — it is safer to flag than to reject.

7

Add a Custom Message (optional)

The system will generate a default error message automatically. If you want a more descriptive message, type it in the last column. Example: Style number must be between 3 and 20 characters

8

Add one row per rule, per field

Each row is a single rule on a single field.

A field can have multiple rules — just add multiple rows with the same field name.

Example: `STYLE_NO` might have `notNull` (critical), `unique` (critical), `maxLength 20` (warning)

✓ TIP Start simple

It's better to have a few clear rules than many uncertain ones. Start with notNull and unique on key fields, then add others based on what the data owner tells you.

TAB

5

Lookups

Translate legacy codes into BlueCherry codes

A **lookup** is a translation table. It tells the migration system: "when you see this code in the source data, replace it with this code in BlueCherry." For example, if Eribé's source data uses **W** for Womens, but BlueCherry expects **WOMENS**, you need a lookup to translate between them.

Do I need a lookup?

You need a lookup whenever a field in Tab 3 has Mapping Type = **lookup**. For each such field, you need one entry on this tab. The lookup can be a small CSV file or a database query.

→ EXAMPLE

Example: DIVISION in the source has values W, M, A

BlueCherry expects: WOMENS, MENS, ACCESSORIES

You create a lookup called 'divisionMap' with a CSV file:

legacyCode,bcCode

W,WOMENS

M,MENS

A,ACCESSORIES

Step-by-Step

1

Review the example lookups in green

The workbook has three example lookups pre-filled. Read through them to understand the structure before adding your own.

2

Identify which lookups you need

Go back to Tab 3. Look for any row where Mapping Type = lookup.
The 'Lookup Name' column on that row tells you what to call the lookup.
Add one row on this tab for each distinct lookup name.

3

Enter the Lookup Name

Type the name exactly as it appears in Tab 3's 'Lookup Name' column.
Use camelCase (no spaces): divisionMap vendorMap seasonMap

4

Select the Source Adapter

How will the lookup data be provided?

csv — you will provide a small CSV file with two columns (key and value)

mssql — the lookup comes from a query on the source SQL database

For most lookups, csv is simplest.

5

Enter the Connection or File Path

For a CSV file: type the path to the file.

Example: `./lookups/division-codes.csv`

For a database: use `${ERIBE_MSSQL}` — Michael will configure the connection.

6

Enter the Source Key Column

This is the column in the lookup file/table that contains the OLD (legacy) code.

Example: if your CSV has columns `legacyCode` and `bcCode`, the key column is `legacyCode`

7

Enter the Source Value Column

This is the column that contains the NEW (BlueCherry) code.

Example: in the same CSV, `bcCode` is the value column.

8

Create the lookup CSV file (if using csv source)

Create a simple two-column CSV file with a header row.

Save it in a `lookups/` folder alongside the workbook.

Include every possible legacy code and its BlueCherry equivalent.

Send the CSV files to Michael along with the completed workbook.

i NOTE Not sure what values to use?

Ask the data owner for a complete list of all codes used in the source system.

Then ask the BlueCherry administrator what codes are configured in BlueCherry.

The mapping between the two is the lookup table.

When You Are Done

Checklist Before Sending

Tab 1 — Entity & Source	Entity type selected, pipeline name entered, source adapter and path set, output path set
Tab 2 — Source Columns	All source columns listed, data types selected, at least 2 example values per column
Tab 3 — Field Mappings	All required BlueCherry columns have a mapping; mapping types are set; key fields have cleanse ops
Tab 4 — DQ Rules	Key fields have at least a notNull rule; severities are set
Tab 5 — Lookups	An entry for every lookup referenced in Tab 3; CSV files created or noted
Open questions	All '?' items noted in the relevant cells or in the Notes fields

How to Send the Completed Workbook

1

Save the workbook

Make sure all changes are saved — use Ctrl+S (Windows) or Cmd+S (Mac).

2

Attach any lookup CSV files

If you created lookup CSV files, include them in the same email or folder.

3

Send to Michael Scott

Email the completed workbook (and any lookup files) to Michael.

Subject line: Eribe intake — [Entity Name] (e.g. Eribe intake — Style)

Michael will review the workbook and contact you with any questions before running the migration.

✓ TIP No need to wait until it's perfect

Send a draft if you are partway through and want Michael to check your approach.

It is much easier to correct the direction early than to rework a finished workbook.

Glossary

Plain-English definitions of terms used in this guide and the workbook.

BlueCherry ERP	The ERP software that Eribé Knitwear is moving to. ERP stands for Enterprise Resource Planning — it's the system that manages orders, stock, suppliers, and styles.
Data Owner	The person at Eribé who works with a particular set of data day-to-day. They know what the data means and where edge cases are.
Entity	A type of data being migrated — for example, Styles is one entity, Vendors is another. You complete one workbook per entity.
Source Data	The data in Eribé's existing system that is being migrated. This could be a database table or a CSV export file.
Field Mapping	Connecting a source column to a BlueCherry column. For example: the source column STYLE_NO becomes the BlueCherry column StyleNo.
DQ (Data Quality)	A set of rules that check whether the source data is clean enough to migrate. Rows that break critical rules are rejected; rows that break warning rules are flagged.
Lookup Table	A translation table that converts old codes to new codes. For example: source code W → BlueCherry code WOMENS.
Pipeline	The automated process that reads source data, checks it, transforms it, and loads it into BlueCherry. The workbook you complete defines how the pipeline works.
YAML	The technical configuration file format used by Sluice. You don't need to understand or write YAML — Michael generates it from your workbook.
Sluice	The ETL tool built by Caracal Lynx that runs the migration. ETL = Extract, Transform, Load — read the data, change it, write it to BlueCherry.
CSV	A simple file format where data is stored as rows of values separated by commas. Often used for data exports from older systems.
Critical	A DQ rule severity level. A critical failure means the row is rejected — it will not be migrated to BlueCherry.
Warning	A DQ rule severity level. A warning failure means the row is flagged in the DQ report but is still migrated to BlueCherry.
Cleanse Operation	An automatic fix applied to a value as part of the migration. For example, trim removes extra spaces; uppercase converts text to capitals.
Adapter	The part of Sluice that connects to a particular type of data source or target. For example, the csv adapter reads CSV files; the mssql adapter connects to SQL Server.
